What is yield farming?

Yield farming lets users earn passive income by supplying crypto to decentralized exchanges, which use liquidity pools for token swaps. Providers earn fees and sometimes governance tokens.

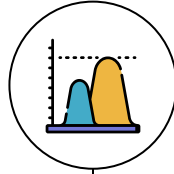

Yield farming of ANY protocols of ANY chains

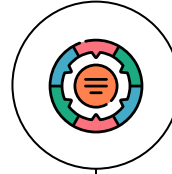

Step 1

Choose the pool without
borders around of any
EVM parachains

Step 2

Send your tokens

Step 3

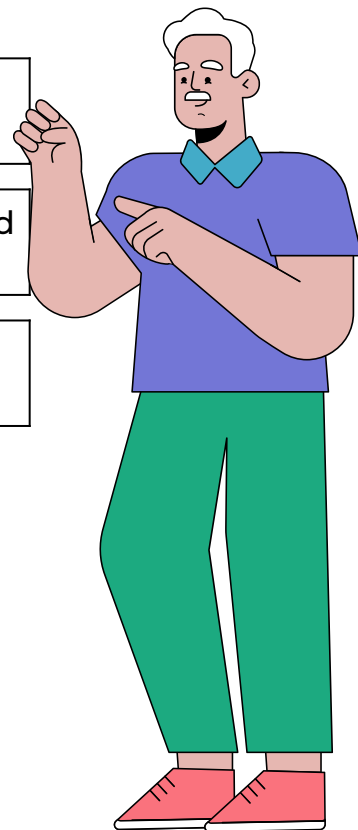

Get rewards

Why finteFarm?

Bridgeless multi-chain yield farming aggregator

01	Bridgeless	Polkadot's native XCM makes this possible without bridges
02	Maximize returns	auto-compounds rewards from lending, staking, and liquidity pools
03	Best APYs	Do NOT requires constant monitoring and manual transactions

What exactly we do for the hackathon time?

Add XCMP to the aggregators contracts

Send tokens from the first parachain to the pool on the second parachain

Deployed contracts and checked the emulation functionality

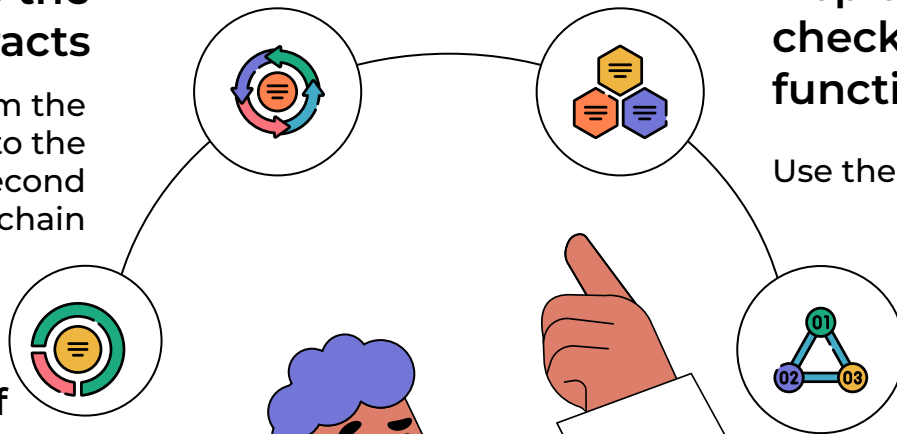

Use the Westend Asset Hub

Everything works

Wait for EVM's DeFi?

Took existing contracts of the aggregator from Ethereum ecosystem

And adopted them to PolkaVM
